

what is useState

In **React**, useState is a **hook** that lets you add and manage state (data that can change) inside a functional component.

Simple explanation

useState lets your component **remember values** and **update the UI when they change**.

What happens here

- count starts at 0
 - Clicking the button calls setCount
 - React updates count
 - The component re-renders with the new value
-

Key points

- Works only inside functional components
- Updating state triggers a re-render
- You should **not modify state directly** (always use the setter function)
